I've been told that Keps are not sufficient to describe the orbit of the
Moon. My understanding is that a Keplerian Element set could be made that
would be valid for a short while (days?) but would quickly drift.

The problem is that the mass of the Moon is *significant* with respect to
the Earth so the center of it's orbit is not at the center of mass of the
Earth. Keplerian element sets (or is it the programs that interpret them?)
don't work for this situation, they were designed for cases where the mass
of the satellite is insignificant compared to the Earth. All man-made
satellites (so far :-)) have a mass that is insignificant relative to the
Earth's mass.

SB SAREX @ AMSAT \$STS-58.002
STS-58 SAREX Mission Lifts Off

The STS-58 mission commenced today with a spectacular liftoff amid sunny skies at the Kennedy Space Center. Liftoff of the Space Shuttle Columbia was 10 seconds late due to an intruding aircraft in the expected Shuttle flight path. As a result, liftoff occurred at 14:53:10 UTC. The primary objective of this 14 day, high inclination (39 degrees) flight is to perform human and animal life science experiments as part of the Spacelab Life Sciences-2 (SLS-2) payload. Also on board is the Shuttle Amateur Radio Experiment (SAREX).

The following represents the latest Keplerian Element set as generated by Gil Carman, WA5NOM, of the Johnson Space Center.

STS-58
1 00058U 93291.67759365 .00119475 00000-0 26040-3 0 88
